

## Geometrical Concepts - Part 2

### 1. Ceva's Theorem

If the lines joining a point  $O$  to the vertices of a triangle  $ABC$  meet the opposite sides in  $D$ ,  $E$ , and  $F$  respectively, then

$$\frac{BD}{DC} \cdot \frac{CE}{EA} \cdot \frac{AF}{FB} = 1.$$

Conversely, if three points  $D$ ,  $E$ , and  $F$  taken on sides  $BC$ ,  $CA$ , and  $AB$  respectively of a triangle  $ABC$  are such that

$$\frac{BD}{DC} \cdot \frac{CE}{EA} \cdot \frac{AF}{FB} = 1$$

holds, then  $AD$ ,  $BE$ , and  $CF$  are concurrent.  
Concurrent lines  $AD$ ,  $BE$ , and  $CF$  are called Cevians.

### 2. Menelaus' Theorem

If three points  $D$ ,  $E$ , and  $F$  taken on suitably extended sides  $BC$ ,  $CA$ , and  $AB$  respectively of a triangle  $ABC$  are collinear, then

$$\frac{BD}{DC} \cdot \frac{CE}{EA} \cdot \frac{AF}{FB} = -1.$$

The minus sign arises from the fact that in this theorem, all the segments are directed. For example  $CA = -AC$ .

Conversely, if three points  $D$ ,  $E$ , and  $F$  taken on suitably extended sides  $BC$ ,  $CA$ , and  $AB$  respectively of a triangle  $ABC$  are such that

$$\frac{BD}{DC} \cdot \frac{CE}{EA} \cdot \frac{AF}{FB} = -1$$

holds, then the points  $D$ ,  $E$ , and  $F$  are collinear.

### 3. Euler Line

The circumcenter  $O$ , the centroid  $G$ , and the orthocenter  $H$  of a non-equilateral triangle are collinear and  $GH = 2OG$ . Line  $OGH$  is called the

Euler line of the triangle.

4. Simson Line

The feet  $K$ ,  $L$ , and  $M$  of perpendiculars from a point  $P$  on the circumcircle of a triangle  $ABC$  on suitably extended sides  $CA$ ,  $AB$ , and  $BC$  respectively are collinear. The line joining  $K$ ,  $L$ , and  $M$  is known as Simson line.

5. Stewart's Theorem

If a line drawn from vertex  $A$  of a triangle  $ABC$  to the opposite side  $BC$  meeting it at  $D$  such that  $BD = m$  and  $DC = n$ , then

$$BC(AD^2 + mn) = m \cdot AC^2 + n \cdot AB^2.$$

If we denote the length of  $AD$  by  $d$  and the lengths of sides  $BC$ ,  $AC$ , and  $AB$  by  $a$ ,  $b$ , and  $c$  respectively, then the above relation is

$$a(d^2 + mn) = mb^2 + nc^2.$$

6. Ptolemy's Theorem

If  $ABCD$  is a cyclic quadrilateral, then

$$AC \cdot BD = AB \cdot CD + BC \cdot AD.$$
